

# Some Considerations for the AT-TPC at NSCL-MSU

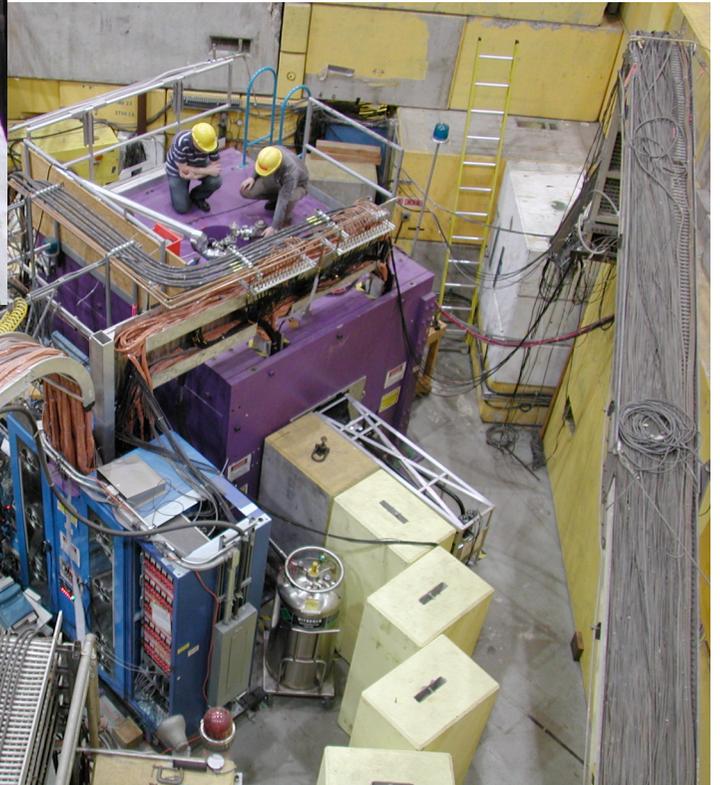

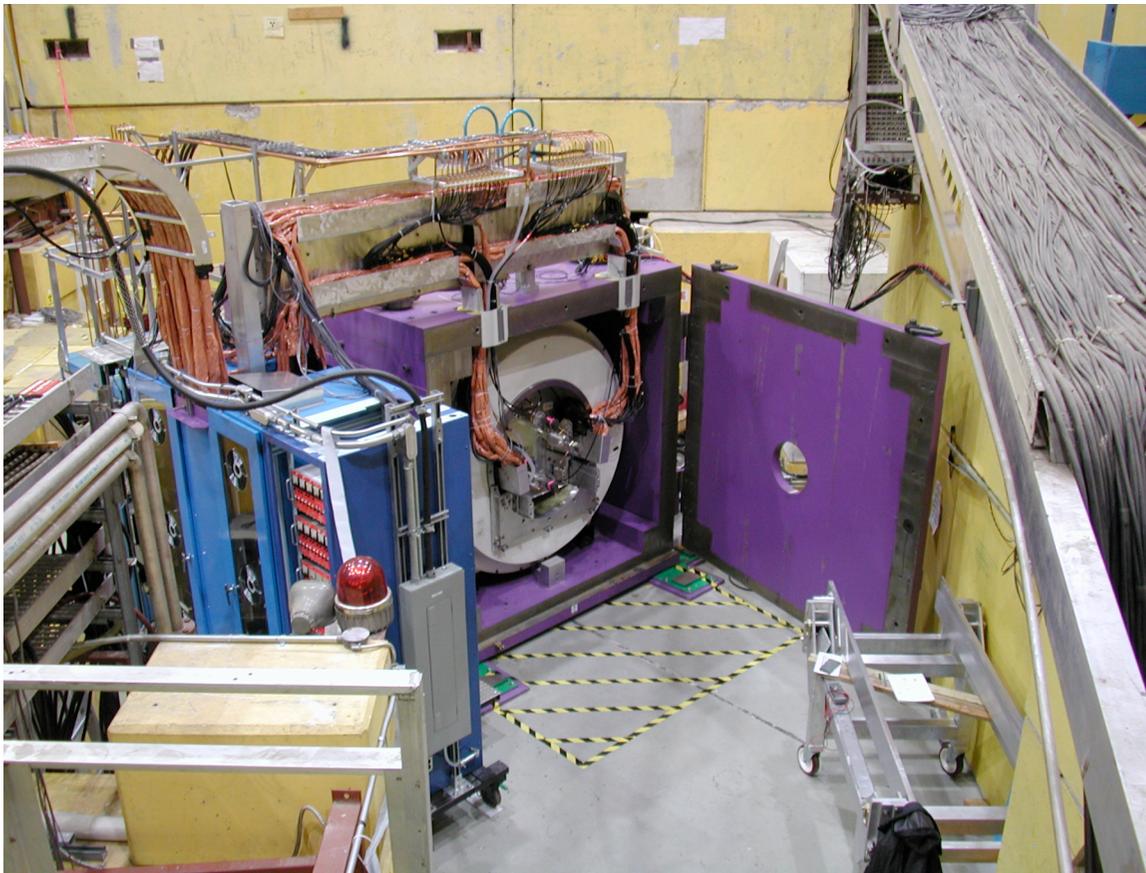

- 1) EOS- Studies: 150MeV/n  $^{108-132}\text{Sn}+\text{Sn}$
- 2) Low to medium energy (1-150MeV/n)  
nuclear structure studies

# Dipole or Solenoid ?

- For the EOS, both solutions should have a maximum open solid angle to forward direction
- High incident beam intensities must be possible

$$\bar{\delta z} = \bar{\delta t} * v_{\text{drift}} = t_{\text{rise}} * (\text{noise/signal}) * v_{\text{drift}} =$$

$$2 * t_{\text{drift}} / \text{nbucket} * (\text{noise/signal}) * v_{\text{drift}} =$$

2 → → 3,4 ??

$$= 2 * L / \text{nbucket} * (\text{noise/signal})$$

This relation is, as it should be, independent on the drift-time.

Hence the expected resolution  $\bar{\delta z} = 2 * L / \text{nbucket} * (\text{noise/signal})$ .

Numerical example:

$L = 1000\text{mm}$ ,  $\text{nbucket} = 128$   $\text{signal/noise} = 50$  ;  $\bar{\delta z} = 0.3\text{mm}$ .

For fast external trigger one would gain a factor 2, this is  $\bar{\delta z} = 0.15\text{mm}$ .

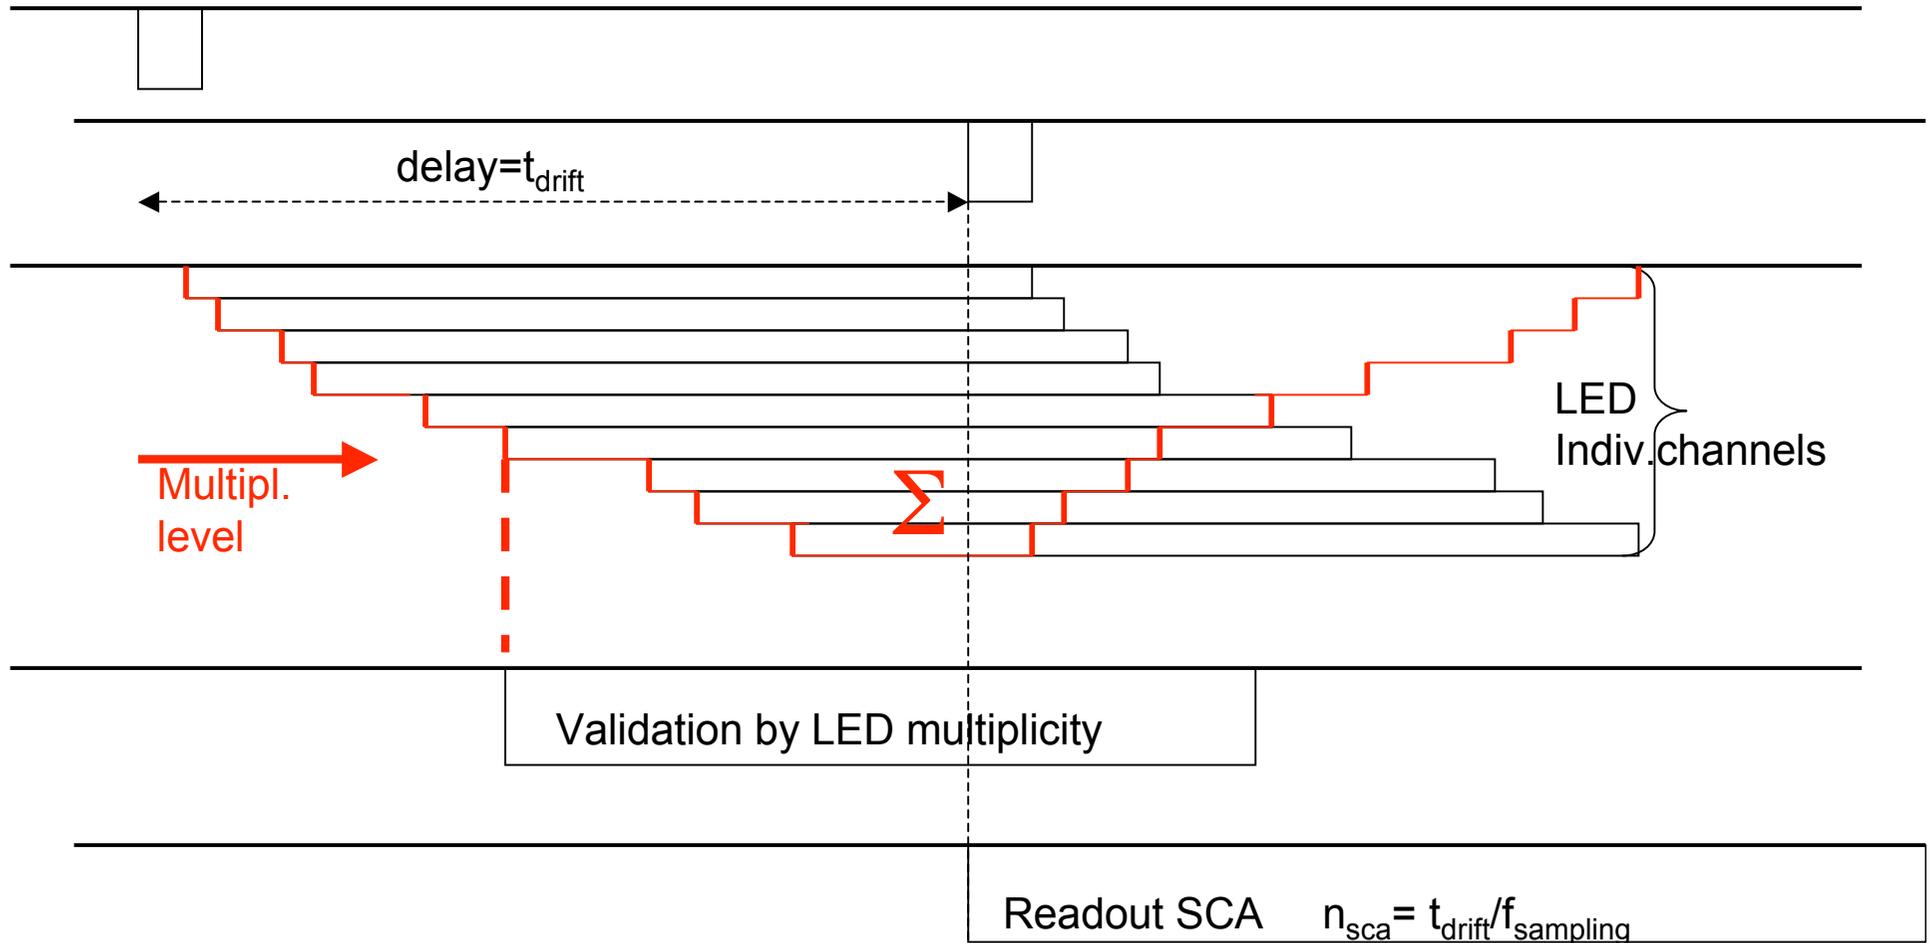

For a particle with low ionization, we considered that  $\text{signal/noise}$  should be at least 10.

$\bar{\delta z} = 1.5\text{mm}$  or  $\bar{\delta z} = 0.75\text{mm}$  respectively.

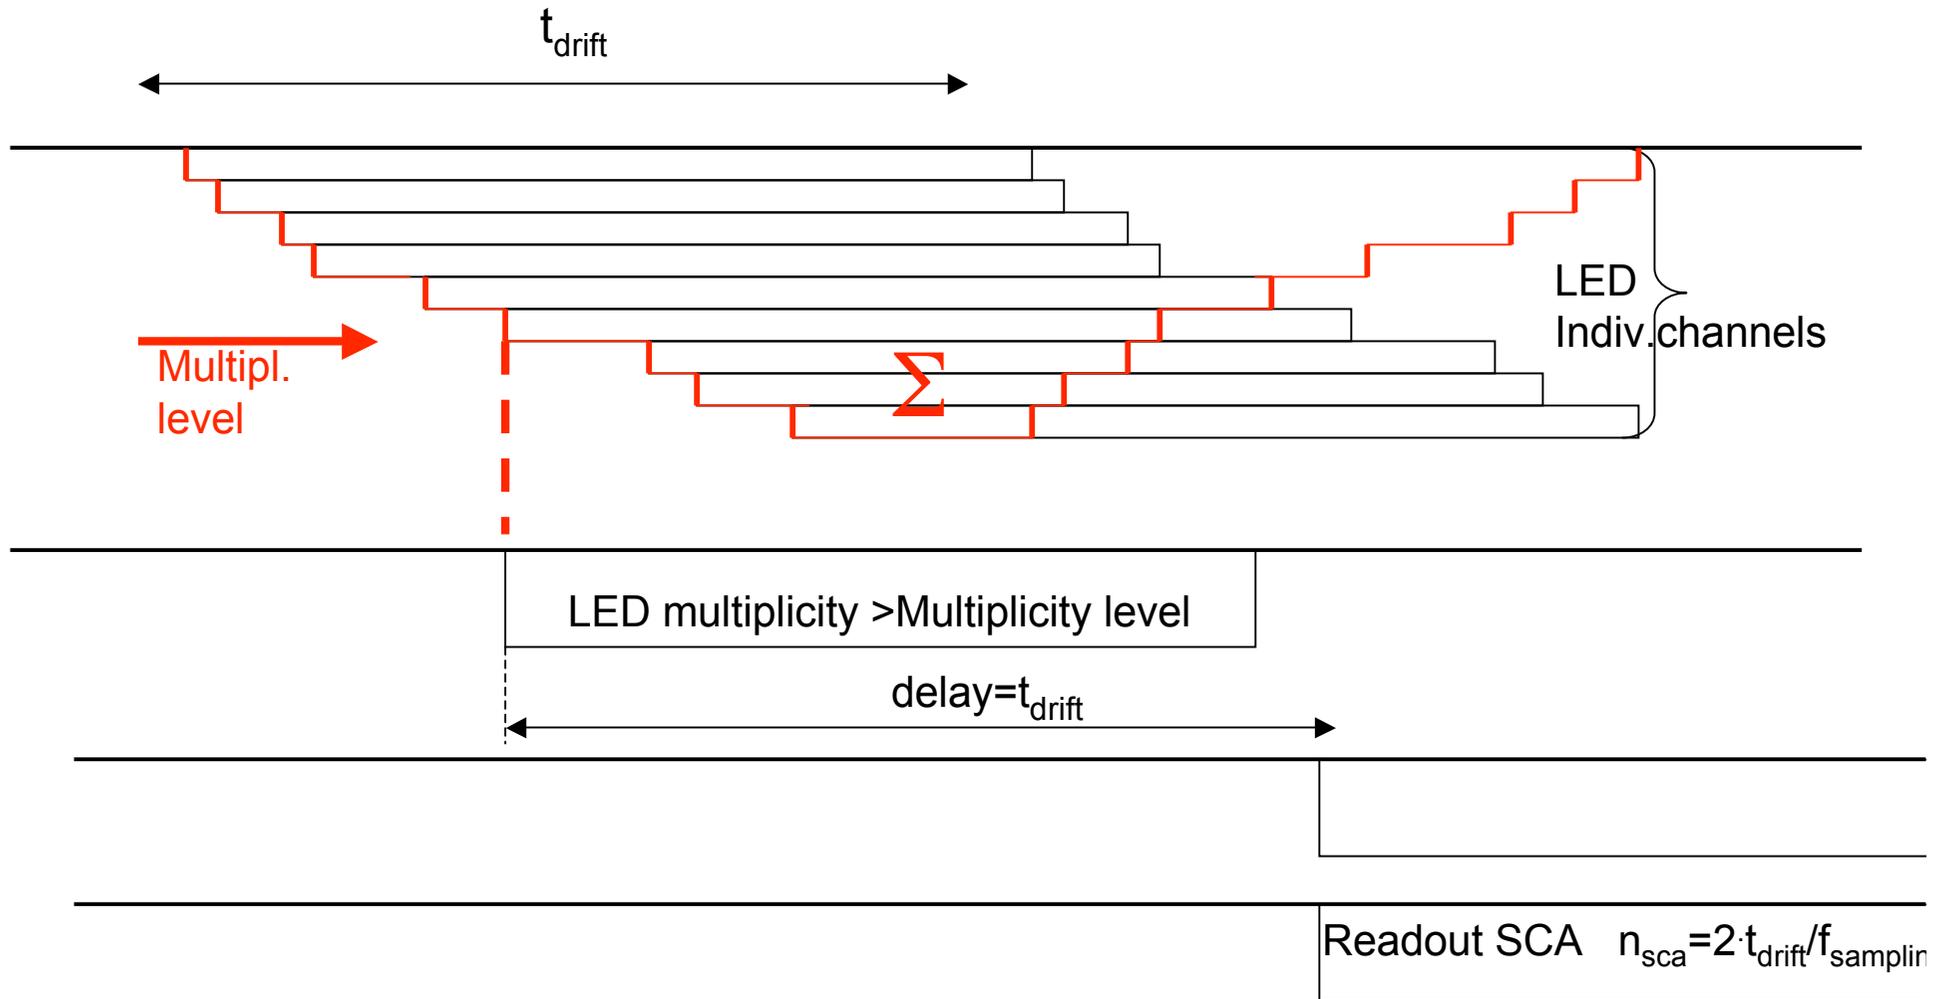

## Working hypotheses

- We tried to find a solution without redoing the FEC + FEM
- Trigger logic based on availability of variable length of SCA (128,256,511 buckets, see previous mails)
- The individual channels give a current output, if not inhibited, during one drift-time(programmable); these currents are summed up and available as output of the after+; they are used in external electronics and it is possible to make a sum of the currents externally
- This results in 2 schematic trigger

External trigger

# Internal multiplicity trigger
